- Practice: Caesar Cipher

# Char

A **char** is a variable type that represents a single character or “glyph”.

```
char letterA = 'A';  
char plus = '+';  
char zero = '0';  
char space = ' ';  
char newLine = '\n';  
char tab = '\t';  
char singleQuote = '\'';  
char backSlash = '\\';
```

# Char

Under the hood, Java represents each **char** as an *integer* (its “ASCII value”).

- Uppercase letters are sequentially numbered
- Lowercase letters are sequentially numbered
- Digits are sequentially numbered

```
char uppercaseA = 'A';           // Actually 65  
char lowercaseA = 'a';           // Actually 97  
char zeroDigit  = '0';           // Actually 48
```

# Char Math!

We can take advantage of Java representing each **char** as an *integer* (its “ASCII value”):

```
boolean areEqual = 'A' == 'A';           // true
boolean earlierLetter = 'f' < 'c';        // false
char uppercaseB = 'A' + 1;
int diff = 'c' - 'a';                      // 2
int numLettersInAlphabet = 'z' - 'a' + 1;
// or
int numLettersInAlphabet = 'z' - 'A' + 1;
```

# Side Note: Type-casting

If we want to force Java to treat an expression as a particular type, we can also *cast it* to that type.

<code>'A' + 1</code>	<code>// evaluates to 66 (int)</code>
<code>(char)('A' + 1)</code>	<code>// evaluates to 'B' (char)</code>
<code>1 / 2</code>	<code>// evaluates to 0 (int)</code>
<code>(double)1 / 2</code>	<code>// evaluates to 0.5 (double)</code>
<code>1 / (double)2</code>	<code>// evaluates to 0.5 (double)</code>

# Character Methods

Method	Description
<code>Character.isDigit(<i>ch</i>)</code>	true if <i>ch</i> is '0' through '9'
<code>Character.isLetter(<i>ch</i>)</code>	true if <i>ch</i> is 'a' through 'z' or 'A' through 'Z'
<code>Character.isLetterOrDigit(<i>ch</i>)</code>	true if <i>ch</i> is 'a' through 'z', 'A' through 'Z' or '0' through '9'
<code>Character.isLowerCase(<i>ch</i>)</code>	true if <i>ch</i> is 'a' through 'z'
<code>Character.isUpperCase(<i>ch</i>)</code>	true if <i>ch</i> is 'A' through 'Z'
<code>Character.toLowerCase(<i>ch</i>)</code>	returns lowercase equivalent of a letter
<code>Character.toUpperCase(<i>ch</i>)</code>	returns uppercase equivalent of a letter
<code>Character.isWhitespace(<i>ch</i>)</code>	true if <i>ch</i> is a space, tab, new line, etc.

Remember: `toLowerCase` and `toUpperCase` **return** the new char; they cannot modify an existing char!

# Strings

A **String** is a variable type representing a sequence of characters.

```
String text = "Hi parents!";
```

<i>index</i>	0	1	2	3	4	5	6	7	8	9	10
<i>character</i>	'H'	'i'	' '	'p'	'a'	'r'	'e'	'n'	't'	's'	'!'

- Each character is assigned an *index*, going from 0 to length-1
- There is a **char** at each index

# Strings vs. Chars

Remember: chars and length-1 strings are different!

char ch = 'A' **DIFFERENT FROM** String str = "A"

'A' + 1

// evaluates to 66 (int)

"A" + 1

// evaluates to "A1" (String)

# Creating Strings

```
String str = "Hello, world!";  
String empty = "";  
println(str);
```

**// Read in text from the user**

```
String name = readLine("What is your name? ");
```

**// String concatenation (using "+")**

```
String message = name + " is " + 2 + " cool.";
```

# From Chars to Strings

```
char c1 = 'a';
```

```
char c2 = 'b';
```

// How do we concatenate these characters?

```
String str = c1 + c2; // ERROR: this is an int!
```

```
String str = "" + c1 + c2; //
```

# Plan For Today

- Practice: Caesar Cipher

# Substrings

A *substring* is a subset of a string.

```
String str = "Hello, world!";  
String hello = str.substring(0, 5);
```

0	1	2	3	4	5	6	7	8	9	10	11	12
'H'	'e'	'l'	'l'	'o'	','	' '	'w'	'o'	'r'	'l'	'd'	'!'

# Substrings

A *substring* is a subset of a string.

```
String str = "Hello, world!";  
String worldExclm = str.substring(7, 13);
```

0	1	2	3	4	5	6	7	8	9	10	11	12
'H'	'e'	'l'	'l'	'o'	','	' '	'w'	'o'	'r'	'l'	'd'	'!'

# Substrings

A *substring* is a subset of a string.

```
String str = "Hello, world!";  
String worldExclm = str.substring(7); // to end
```

0	1	2	3	4	5	6	7	8	9	10	11	12
'H'	'e'	'l'	'l'	'o'	','	' '	'w'	'o'	'r'	'l'	'd'	'!'

# String Methods

Method name	Description
<code>s.length()</code>	number of characters in this string
<code>s.charAt(<i>index</i>)</code>	char at the given index
<code>s.indexOf(<i>str</i>)</code>	index where the start of the given string appears in this string (-1 if not found)
<code>s.substring(<i>index1</i>, <i>index2</i>)</code> or <code>s.substring(<i>index1</i>)</code>	the characters in this string from <i>index1</i> (inclusive) to <i>index2</i> ( <u>exclusive</u> ); if <i>index2</i> is omitted, goes until end
<code>s.toLowerCase()</code>	a new string with all lowercase letters
<code>s.toUpperCase()</code>	a new string with all uppercase letters

- These methods are called using **dot notation**:

```
String className = "CS 106yay!";  
println(className.length());    // 10
```

# Strings are Immutable

Once you create a String, its contents **cannot be changed**.

// Cannot change individual chars in the string

```
String typo = "Hello, world!";
```

```
typo.charAt(8) = 'o'; // Error! Will not run.
```

To change a String, you must create a *new* String containing the value you want (possibly using String methods).

```
String corrected = typo.substring(0, 8) +  
                    'o' + typo.substring(9);
```

# Strings are Immutable

```
String className = "cs 106a";  
className.toUpperCase();           // does nothing!
```

```
className = className.toUpperCase(); //  
println(className);                // CS 106A
```

# Comparing Strings

```
String greeting = "Hello!";  
if (greeting == "Hello!") {    // Doesn't work!  
    ...  
}
```

// Instead:

```
if (greeting.equals("Hello!")) {  
    ...  
}
```

*Always use .equals instead of == and !=*

# Comparing Strings

Method	Description
<code>s1.equals(s2)</code>	whether two strings contain the same characters
<code>s1.equalsIgnoreCase(s2)</code>	whether two strings contain the same characters, ignoring upper vs. lower case
<code>s1.startsWith(s2)</code>	whether <b>s1</b> contains <b>s2</b> 's characters at start
<code>s1.endsWith(s2)</code>	whether <b>s1</b> contains <b>s2</b> 's characters at end
<code>s1.contains(s2)</code>	whether <b>s2</b> is found within <b>s1</b>

# Looping Over Strings

A common String programming pattern is looping over a string and operating on each character.

```
String str = "Hello!";  
for (int i = 0; i < str.length(); i++) {  
    char ch = str.charAt(i);  
    // Do something with ch here  
}
```

# Looping Over Strings

A common String programming pattern is looping over a string and operating on each character.

**// Prints out each letter on a separate line**

```
String str = "Hello!";  
for (int i = 0; i < str.length(); i++) {  
    char ch = str.charAt(i);  
    println(ch);  
}
```

# Looping Over Strings

A common String programming pattern is looping over a string and operating on each character.

```
// Creates a new String in all caps
```

```
String str = "Hello!";
```

```
String newStr = "";
```

```
for (int i = 0; i < str.length(); i++) {
```

```
    char ch = str.charAt(i);
```

```
    newStr = newStr + Character.toUpperCase(ch);
```

```
}
```

```
println(newStr);
```

```
// HELLO!
```

# Looping Over Strings

A common String programming pattern is looping over a string and operating on each character.

```
// Creates a new String in all caps
String str = "Hello!";
String newStr = "";
for (int i = 0; i < str.length(); i++) {
    char ch = str.charAt(i);
    newStr += Character.toUpperCase(ch);
}
println(newStr);           // HELLO!
```

# Building Up New Strings

Another common String programming pattern is building up a new string by adding characters to it over time.

```
// Creates a new String in all caps
```

```
String str = "";
```

```
for (int i = 0; i < 5; i++) {
```

```
    str += i;
```

```
}
```

```
println(str);           // 01234
```

- Practice: Palindromes
- Practice: Caesar Cipher

# Exercise: Reversing a String

Let's write a method called **reverseString** that takes one String parameter, and returns a new String with the characters in the opposite order.

```
reverseString("Hello!") -> "!olleH"
```

# Reversing a String

# Reversing a String

H e l l o !

---	---	---	---	---	---

!	o	l	l	e	H
---	---	---	---	---	---

# Reversing a String

```
String str = "Hello!";  
String newStr = "";  
for (??? ; ??? ; ???) {  
    ...  
}
```

# Reversing a String

```
String str = "Hello!";  
String newStr = "";  
for (int i = str.length() - 1; ??? ; ???) {  
    ...  
}
```

# Reversing a String

```
String str = "Hello!";  
String newStr = "";  
for (int i = str.length() - 1; i >= 0; ???) {  
    ...  
}
```

# Reversing a String

```
String str = "Hello!";  
String newStr = "";  
for (int i = str.length() - 1; i >= 0; i--) {  
    ...  
}
```

# Reversing a String

```
String str = "Hello!";  
String newStr = "";  
for (int i = str.length() - 1; i >= 0; i--) {  
    newStr += str.charAt(i);  
}
```

- More Strings
- Practice: Reversing a String
- **Practice: Palindromes**
- Practice: Caesar Cipher

# Exercise: Palindromes

Let's write a method called **isPalindrome** that takes one String parameter, and returns whether or not that String is a palindrome (the same forwards and backwards).

```
isPalindrome("racecar") -> true
```

```
isPalindrome("hi there") -> false
```

```
isPalindrome("kayak") -> true
```

# Plan For Today
